Figure 1: Screenshot of WebPlotDigitizer showing the data points recovered on a plot via automatic detection.

# 1   Introduction

A large quantity of useful information is available only as plotted data points in an image. In these images, it is easy to determine the relationship between the variables involved, but recovering the exact numerical values of the data is usually a tedious and error prone process. To aid this time consuming task of data recovery, many digitization softwares have been developed over the years. However, even with the abundance of free and commercial softwares, this task remains daunting and prone to errors. Many of the existing softwares are either designed to work only on specific operating systems or work with a limited variety of plots. Some are just difficult to use or prone to errors. Finally, many require a paid license which prevents their widespread use by students, independent researchers or organizations with limited resources.

Because of the above limitations in current digitizing softwares, WebPlotDigitizer was developed to facilitate easy and accurate data extraction from a variety of plot types and also maps. This program has been built using HTML5 which allows it to run within most popular web browsers and does not require an installation process that is performed by the user. This is distributed free of charge as an opensource software. A screenshot of a typical session of the software is shown in Figure 1.

## 1.1   History

WebPlotDigitizer was initially developed while working on my graduate studies at the University of Notre Dame. Having to extract data from many publications for comparing and contrasting my own

findings in the lab was a time consuming task. The search for a tool to aid this process usually ended in realizing that most of the existing softwares for this purpose did not fulfill many of the requirements. I was faced with a similar task as an undergraduate student. Back then, just writing a simple Java based code for picking a few points by clicking on them manually was sufficient. My advisor at Notre Dame also had a Matlab code to do this job for two dimensional XY plots, but the points still had to be picked manually. None of these options were very convenient.

Some of the experimental work in the lab required me to learn some basic image processing techniques which eventually formed the basis of the automatic detection algorithms used here. Image processing knowledge along with some interest in learning the very popular HTML5 APIs were a perfect match to create a web based data extraction tool like this.

WebPlotDigitizer is now used by hundreds of people everyday and because of this interest, I have continued to refine the software in my spare time.

## 1.2   User Manual and Tutorials

This user manual describes the various capabilities of the software and aims to help the user in making an effective use of the software. This manual may be updated continuously to match the latest deployed version of the software. A few video tutorials for the previous version of the software are available at `http://arohatgi.info/WebPlotDigitizer`. Other resources to find technical information about the software are also being considered.

## 1.3   License

WebPlotDigitizer is distributed under GNU General Public License version 3 by Ankit Rohatgi. For complete terms and conditions, please refer to `http://www.gnu.org/copyleft/gpl.html`

## 1.4   Source Code

WebPlotDigitizer is an open source software (see above). The source code can be obtained from GitHub (`https://github.com/ankitrohatgi/WebPlotDigitizer/`). Feel free to contact via email if you wish to contribute to this project.

## 1.5   Availability

The latest released version of the software can be used directly from the website `http://arohatgi.info/WebPlotDigitizer`. For the Google Chrome web browser, an *app* pointing to the online software is also available at the Chrome App Store (`https://chrome.google.com/webstore/category/apps`).

## 1.6   Supported Browsers

Version 3.3 was ensured to work without major issues on the following browsers:

- Safari 7.0.4 on Mac OS 10.9.3

- Google Chrome 35 on Mac OS 10.9.3

- Google Chrome on Windows 7 32-bit

- Firefox 24.0 on Windows 7 32-bit

- Internet Explorer 11 on Windows 7 32-bit

- Firefox 24.0 on Xubuntu Linux 14.04 32-bit

It is expected that browsers similar in functionality and support for the HTML5 API should not have any major problems executing the version 3.3.

## 1.7 Citing WebPlotDigitizer

If you wish to cite WebPlotDigitizer in any of your works, then please use the following information:

| | |
|---:|---|
| Author | Ankit Rohatgi |
| Title | WebPlotDigitizer |
| Website | `http://arohatgi.info/WebPlotDigitizer` |
| Version | 3.3 |
| Date | June, 2014 |
| E-Mail | ankitrohatgi@hotmail.com |

## 1.8 Reporting Issues

In case of issues with the data recovery, access to the software or general technical questions, feel free to contact via e-mail. Issues specific to bugs in the software can also be reported on the issues page on GitHub: `https://github.com/ankitrohatgi/WebPlotDigitizer/issues`

## 1.9 Data Privacy

WebPlotDigitizer's image analysis code runs entirely on the user's computer and does not store the loaded images or data on to any server. When *Graph in Plotly* option is selected, the digitized data is transmitted to Plotly (`http://plot.ly`) servers.

## 1.10 Funding

WebPlotDigitizer is not funded by any organization. PayPal donations from the website and my personal time and effort are responsible for keeping this project afloat.

# 2 Loading Plots

The image file containing the figure to be analyzed can be loaded into the software in the following ways:

1. **Drag & Drop Operation:** Image can be dragged and dropped from the file browser on to the image viewing area of the application.

2. **File Menu → Load Image:** Browse for a file on the hard disk to load.

Figure 2: The top row of buttons in WebPlotDigitizer.

3. **Copy-Paste from Clipboard:** This is only supported in Google Chrome web browser. An image selected by copying in a PDF or an image viewer can be pasted on to the software via a simple copy-paste operation.

4. **File Menu → Webcam Capture:** A snapshot taken from the webcam can also be used. For best results, the webcam should be pointed directly along the normal to the plot surface. In the future, some image transformation features might be added to WebPlotDigitizer to compensate for the distortions.

## 2.1 Supported Image Formats

WebPlotDigitizer relies on the image formats supported by the HTML5 *canvas* element. Most browsers support common image formats such as JPEG, PNG, BMP and GIF. Since the support for an image format depends on the browser used to access the software, please refer to your browser's manual for details. For popular browsers, you can also refer to Wikipedia (`http://en.wikipedia.org/wiki/Comparison_of_web_browsers#Image_format_support`).

# 3 Define Axes

After loading the desired image, you should specify the type of axes that is used in the plot. This step is required for the software to correctly map the image pixels to possible data points in the image. Depending on the plot type, you will have to select a few known points on the axes. On clicking the *Axes → Define Axes* menu item (see Figure 2), you should be presented with the menu shown in Figure 3.

## 3.1 2D (X-Y) Plot

Most plots that are on a two dimensional cartesian coordinate system fall under this category. Two dimensional plots that are skewed such that the axes are not mutually perpendicular will also work. Also, neither the horizontal or the vertical axes need to be perfectly aligned with the horizontal and vertical lines of the computer. An image rotated by an angle should also work.

On selecting this option, you should be presented with a popup window which asks you to click on two points on the horizontal axis and two points on the vertical axis. After clicking *Proceed* on that popup, click on two points on one of the two axes $(x_1, x_2)$ and two on the other $(y_1, y_2)$. For
Figure 3: Popup with plot types that are supported in the software.

(a) Mark four points to align axes

(b) Specify values

Figure 4: Alignment for 2D (X-Y) Plot.

better accuracy during the digitization process, pick the points that are as far away from each other as possible. Also, remember the $(x_1, x_2)$ and $(y_1, y_2)$ values on the axes as you will be required to enter those once four points have been clicked on. You can also make fine adjustments to the location of a calibration point highlighted in green using keyboard cursor keys. Pressing the Shift key along with the cursor keys will move the point at a faster rate. To highlight the point to be adjusted, you can also click near the point after selecting the four required points.

After the four points have been clicked on, press *Continue* and another popup window will appear where you will be required to enter the values at these points. This helps the software map the image pixels corresponding to data points to their actual values when the image is digitized.

### 3.1.1 Format of Calibration Values

Like most computer programs, WebPlotDigitizer accepts integers (e.g. 1, 2, 3 etc.) or floating point numbers (e.g. 3.14159). Some extra things to keep in mind are as follows:

(a) Mark three points to align axes  (b) Specify values

Figure 5: Alignment for Polar Diagram.

1. Fractions (e.g. 1/2) are not computed as numbers.

2. For exponentials, the caret symbol (ˆ) is not recognized and the values have to be entered as 1.45e-10 for $1.45 \times 10^{-10}$ (for example).

3. **Dates:** This is enabled only for 2D (X-Y) Plots. At the time of calibration, the dates have to be entered in the format shown below. With the final digitized data, however, results can be formatted in many different ways (see section 5.2).

| Date | Format | Examples |
|---|---|---|
| Year, Month and Date | YYYY/MM/DD | 2012/10/23, 2012/10/5 or 2012/10/05 |
| Year, Month | YYYY/MM | 2012/10 or 1989/5 |
| Year | YYYY | 2012 (treated as any integer) |

## 3.2 Polar Diagram

Select this option if the data points in the image are plotted on a polar axes. On selecting this, you will be required to click on three known points including the center of the polar diagram (Figure 5). After clicking on 3 points, you can also select the axes orientation and select Degrees or Radians for the angle. The values entered here also have to follow the format similar to 2D (X-Y) Plots. Dates are not parsed here.

## 3.3 Ternary Diagram

Ternary phase diagrams are typically harder to read than simple two dimensional cartesian or polar plots. Using this software to recover data makes the process of data recovery extremely straightforward and thus reduces the possibility of misinterpreting the data. For this type of plot, simply mark the

(a) Mark three points to align axes          (b) Specify values

Figure 6: Alignment for Ternary Diagram.

three corners as shown in the instructions and then specify the range of variables and orientation of the diagram (Figure 6).

## 3.4 Map With Scale Bar

This plot type is similar to 2D (X-Y) Plots and is provided only as a convenience for images that only have scale information (e.g. microscope images or maps). To calibrate this plot type, simply click on the two ends of the scale bar and enter the scale value without units (Figure 7). The coordinates reported by the software assume the origin to be located at the bottom left of the image. The (x,y) values that are generated are scaled by the scaled factor entered during calibration.

## 3.5 Image (Align to Image Pixels)

This plot type is similar to the Map plot type and is also provided as a convenience over the generic 2D (X-Y) plots. If you select this type, no calibration information is required as the software will calibrate the on-screen pixels to the pixels on the image automatically. This plot type is useful for looking up exact pixel location of a feature in an image.

# 4 Acquire Data

Once the plot axes have been calibrated, you can begin selecting data points on the image. Also note that the numbers below the zoom window reflect actual data coordinates corresponding to your mouse position on the image. If you see incorrect numbers here, then perhaps incorrect calibration values were entered. You must repeat the axes calibration in this situation.
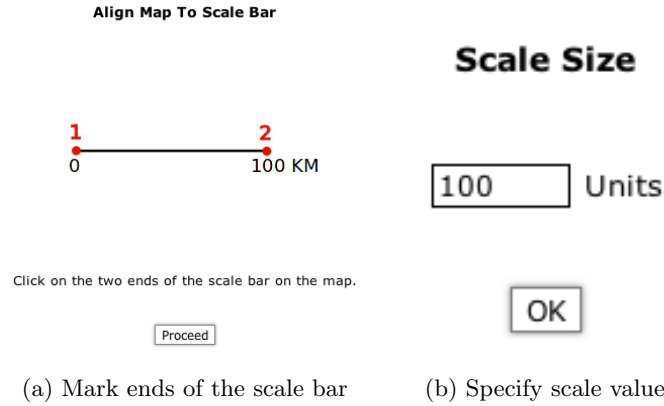

(a) Mark ends of the scale bar     (b) Specify scale value

Figure 7: Alignment for maps and microscope images.

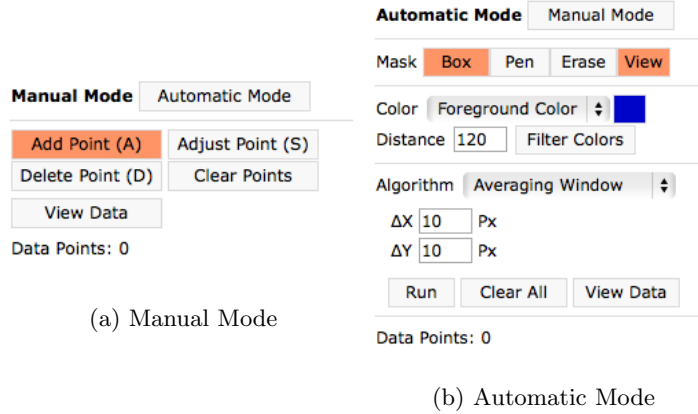

(a) Manual Mode

(b) Automatic Mode

Figure 8: Data acquisition controls.

WebPlotDigitizer should also show a side panel with the data acquisition controls (Figure 8) when the axes are aligned. This sidebar can also be brought up by clicking on the *Acquire Data* button. The data acquisition can be done in either manual or automatic mode. You can alternate between the two modes at any time. In the manual mode you can click on the image to add data points or remove some of the digitized data points. In the automatic mode, you can set up an extraction algorithm that can differentiate between the data points and the image background and mark several data points in a short time.

## 4.1   Manual Mode

The buttons available in this mode are as follows

1. **Automatic Mode:** Switch to automatic extraction mode.

2. **Add Point (A):** After clicking this button or pressing the 'A' key, you can click in the image area to add data points. Any point added on the image will automatically be converted from on-screen pixels to data values utilizing the axes calibration.

3. **Adjust Point (S):** After clicking this or pressing the 'S' key, you can click on an existing data point to select it. The selected point can then be repositioned using the cursor keys on the keyboard. Press Shift+Cursor key for a faster rate of movement.

4. **Delete Point (D):** After clicking this button or pressing the 'D' key, you can click on a previously added data point to delete it.

5. **Clear Points:** This deletes all data points added on the image. This does not clear the axes calibration.

6. **View Data:** This launches a popup dialog where the collected data can be viewed, exported to a CSV file or Plotly.

## 4.2   Automatic Mode

The controls available in the automatic mode are used for selecting the appropriate algorithm and providing the necessary inputs required for automated extraction of data points. Detailed steps required to extract data using this mode are described later in this section. The purpose of the various controls available in this mode is as follows:

1. **Manual Mode:** Switch to manual mode. You can switch between these modes at any time.

2. **Mask Controls:**

   (a) **Box:** This is used to mark a rectangular region to be used during the search for data points.

   (b) **Pen:** This is used for marking areas of the image to be included in the search for data points via free hand drawing.

   (c) **Erase:** This is used to unmark the areas marked using the *Box* or *Pen* tools.

   (d) **View:** This is used to simply view the marked search region.

3. **Color Controls:** For automatic extraction, you either need to specify the foreground color of the data or the background color.

   (a) **Foreground/Background Color Selection:** Select the appropriate option from the drop-down menu and click on the colored button on the right to show a popup for color selection. The popup dialog also shows a list of most dominant colors at the bottom that can be selected.

   (b) **Distance:** Change this value to adjust the range of colors around the selected color to be accepted as foreground or background.

   (c) **Filter Colors:** Test the color selection and the specified distance value. The area highlighted in yellow is the region that will finally be used by the automatic extraction algorithms.

4. **Algorithm Selection:** Select the appropriate algorithm depending on the application. Each algorithm is described in detail below.

5. **Run:** Start the auto-detection algorithm. After this is completed, the detected points should appear over the image.

6. **Clear All:** Clear all data points.

7. **View Data:** This launches a popup dialog where the data can be viewed and exported to a CSV file or Plotly.

### 4.2.1 Differentiating Data From Background

Automatic data extraction relies on separating the color of the data points or curves from the background in the image. The extraction algorithms can work in two modes of color extraction: Foreground mode and Background mode. In the foreground mode, the algorithms look for the foreground color specified for the data and ignore everything else. In the background mode, the algorithms include everything except the background color as potential data points. If the data points or curves of interest are uniformly colored (approximately), then the foreground mode may be more suitable. Otherwise if the background is uniformly colored (approximately) and the curve or data points are not then the background mode may me more suitable.

### 4.2.2 Mark Region of Interest (Mask)

The extraction algorithms also need to know the region of the image to be searched for the specified colors. The software does not search the entire image as in many cases, the data point or the curve colors may be repeated in non-data parts of the image. To specify the region of interest, use the *Box*, *Pen* and *Erase* tools to paint over a yellow mask over the data part of the image as shown in Figure 9. The extraction algorithms will look for data only under the yellow colored region.

## 4.3  Digitization Algorithms

Four different digitization algorithms are available in WebPlotDigitizer as shown in Figure 10. The *Averaging Window* algorithm is set as the default as it is usually suitable for many plot types. The other algorithms are more suited for 2D (X-Y) plots, but may be useful in other cases too. These algorithms are under active development and a few shortcommings with the current algorithms should get addressed in the future versions.

### 4.3.1 Averaging Window

As mentioned above, this is probably the most useful algorithm and is useful across many plot types. This algorithm finds the mean position of a colored region that can fit in a rectangular region that is $\Delta X$ pixels (on-screen) wide and $\Delta Y$ pixels (on-screen) tall. As a user, you should increase the size of the box for thick lines or large data points and decrease it for thin lines. If you see multiple points incorrectly detected across the width of a thick data curve, then you need to increase the numbers specified here. The fact that this requires on-screen pixels may be changed in the future so that the values in actual units in the current axes can be specified.
Figure 9: Use the *Box*, *Pen* and *Erase* tools to mark the region containing the required data (automatic extraction).

(a) Averaging Window

(b) X Step

(c) Y Step

(d) X Step With Actual Units

Figure 10: Four automatic extraction algorithms are available. These are subject to change in the future releases.

### 4.3.2 X Step

This algorithm starts on the left side of the image and scans in the vertical direction. After detecting the first set of data, this jumps $\Delta X$ pixels (on-screen) to the right. In the vertical direction, it picks points by finding average position of colored pixels that fall within the *Line Width* of each other. So for thick curves or data points, increase the value specified for *Line Width*.

Due to limited utility of this algorithm, this may be removed or replaced in the future versions of the software.

### 4.3.3 Y Step

This is similar to the X Step algorithm, but this starts scanning from the bottom of the image and moves up scanning horizontally. Again, due to somewhat limited utility of this algorithm, this may be removed or replaced in the future versions of the software.

### 4.3.4 X Step With Actual Units

This algorithm works only for 2D (X-Y) plots at the moment. This is an improved version of the X Step algorithm as the exact scanning positions on the X axis can be specified in the data units. This is often useful while comparing values from two sets of data on the same image. Specify the range of values in X and Y axis to look for data by setting $X_{min}, X_{max}, Y_{min}$ and $Y_{max}$. Set $\Delta X$ to set the step size in X direction. The width of the curve (*Line Width*) still needs to be specified in terms of on-screen pixels.

## 5 Handling Digitized Data

Once the required data points are marked on the image using the manual mode, automatic mode or a combination of both, the digitized values can be seen by clicking the *Create .CSV* button. This presents a popup window as shown in Figure 11. Here, the digitized values can be sorted by the variable or in order of the distance between the points (Nearest Neighbor). The values can also be copied and used in common data analysis softwares. Recently, an option to send these values over to another cloud based data analysis and graphing software called Plotly (`http://plot.ly`) has also been added.

### 5.1 Sort Data

The digitized data can be left unsorted (Raw Output) or by one of the axes variables in ascending or descending order. The Nearest Neighbor option sorts the data depending on the distance of the points from each other.

### 5.2 Formatting Dates

If one or both of the axes in a 2D (X-Y) plot contain dates then fields to specify the output format of the values are also shown (Figure 12). In these fields, the following pieces of text are replaced with the corresponding part of the date to format the text (case insensitive):
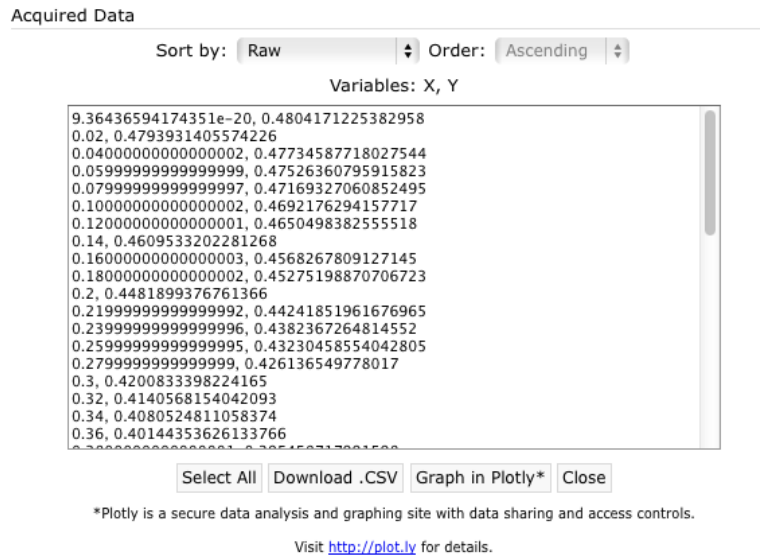

Figure 11: CSV formatted digitized data. This can be sorted, pasted to a .CSV file or graphed in Plotly.

Figure 12: Field to specify formatting of dates. This appears on X, Y or both axes depending on which variables contained dates at the time of axes calibration.

| Text | Replaced With | Example |
|------|---------------|---------|
| YYYY or yyyy | Year, all digits | 2012 |
| YY or yy | Year, last two digits | 98 for 1998 |
| MMMM or mmmm | Month, full name | January |
| MMM or mmm | Month, short name | Jan |
| MM or mm | Month, numeric | 10 |
| DD or dd | Date | 23 |

A few examples are shown below:

| Format Field Text | Date Shown (Example) |
|-------------------|----------------------|
| dd-mm-yyyy | 23-10-2012 |
| mmm-yyyy | Oct-2012 |
| yyyy abc mmmm | 2012 abc October |
| mmm 'yy | Oct '12 |

## 5.3 Export to .CSV File

Comma-Separated Values (CSV) format files are simple text files containing tabular data. Each row of line corresponds to a table row and the column values are separated by a character or a string (usually just a comma)[1]. Due to its simplicity, CSV format is supported in most data analysis softwares like Microsoft Excel, Matlab etc.

To save the values from WebPlotDigitizer into a CSV file, all you have to do is open your favorite text editor (e.g. Notepad on Microsoft Windows) and Copy-Paste the values shown in the results popup window. Save the file with a .CSV file extension. You can now use this file in your favorite data analysis software.

---

[1]For more information on CSV format, check out `http://en.wikipedia.org/wiki/Comma-separated_values`
